Disclaimer

Highmark WholecareSM medical policy is intended to serve only as a general reference resource regarding coverage for the services described. This policy does not constitute medical advice and is not intended to govern or otherwise influence medical decisions.

Policy Statement

Highmark WholecareSM may provide coverage under the medical-surgical benefits of the Company's Medicaid products for medically necessary Vitamin D deficiency testing.

This policy is designed to address medical necessity guidelines that are appropriate for the majority of individuals with a particular disease, illness or condition. Each person's unique clinical circumstances warrant individual consideration, based upon review of applicable medical records.

(Current applicable Pennsylvania HealthChoices Agreement Section V. Program Requirements, B. Prior Authorization of Services, 1. General Prior Authorization Requirements.)

Definitions

Ultraviolet B (UVB) – Ultraviolet radiation with wavelengths between 290 and 320 nm, comprising less than 1 percent of the ultraviolet radiation that reaches the earth's surface. Ultraviolet B causes sunburn and a number of damaging photochemical changes within cells, including damage to DNA, leading to premature aging of the skin, premalignant and malignant changes, and a variety of photosensitivity reactions; it is also used therapeutically for treatment of skin disorders.

Hypervitaminosis – A condition in which the amount of vitamins stored in our body overpasses the normal recommended level of vitamins, poisoning the body.

Vitamin D deficiency - a 25(OH)D below 20 ng/ml (50 nmol/liter), and vitamin D insufficiency as a 25(OH)D of 21–29 ng/ml(525–725 nmol/liter).

Vitamin D metabolites are used to assess serum vitamin D level and metabolism. Specifically, 25-hydroxy vitamin D, referred to as 25(OH)D, and 1,25-dihydroxyvitamin D. The 25 (OH)D metabolite has an estimated half- life of approximately two (2) to three (3) weeks and provides a measure of the vitamin D originating from both dietary/supplement sources and from cutaneous(e.g. sun exposure) production. Vitamin D stored in other body tissues are, however, not reflected in the serum 25(OH)D levels. Serum levels of the active vitamin D metabolite, 1,25-dihydroxyvitamin D, may not accurately indicate the individual's vitamin D status due to its short half-life (15 hours). Since it's closely regulated by parathyroid hormone and the intake of calcium and phosphate, serum levels of 1,25-dihydroxyvitamin D may appear normal in individuals with vitamin D deficiency.

Procedures

1. Measurement of cholecalciferol 25-hydroxyvitamin D (25 [OH] D) levels (CPT code 82306) may be considered medically necessary for individuals with ANY of the following (not all inclusive):
 - A. Clinically documented underlying disease that is specifically associated with vitamin D deficiency, decreased bone density; OR
 - B. Individuals whose vitamin D supplementation is being taken per the recommended daily amounts AND who are considered high risk for vitamin D deficiency, such as:
 - 1) African American and Hispanic children or adults; OR
 - 2) Pregnant or lactating women; OR
 - 3) Older adults greater than 65 years with a history of falls or non-traumatic fractures; OR
 - 4) Obese children or adults (BMI greater than or equal to 30); OR
 - C. Chronic kidney disease (CKD), stage 3 or greater; OR
 - D. Granuloma forming diseases:
 - 1) Sarcoidosis; OR
 - 2) Tuberculosis; OR
 - 3) Histoplasmosis; OR
 - 4) Coccidiomycosis; OR
 - 5) Berylliosis; OR
 - E. Hepatic disease or failure; OR
 - F. Hyperparathyroidism; OR
 - G. Long term use of anticonvulsants, glucocorticoids, rifampicin, AIDS medications, antifungals, cholestyramine, or other medications known to lower vitamin D levels; OR
 - H. Malabsorption states:
 - 1) Cystic fibrosis; OR
 - 2) Inflammatory bowel disease (i.e., Crohn's disease, ulcerative colitis); OR
 - 3) Bariatric surgery; OR
 - 4) Radiation enteritis; OR
 - I. Individuals receiving hyperalimentation; OR
 - J. Osteomalacia; OR
 - K. Osteoporosis or at risk of developing osteoporosis; OR
 - L. Osteogenesis imperfecta; OR
 - M. Rickets; OR
 - N. Vitamin D deficiency on replacement therapy, to monitor the efficacy of treatment.

2. The testing of cholecalciferol 1,25-dihydroxy (Vitamin D) (CPT code 82652) may be considered medically necessary for the evaluation of individuals with a clinically documented underlying disease or condition associated with increased or decreased 1,25 dihydroxy, including ANY of the following:
 - A. Chronic kidney disease; OR
 - B. Hypercalcemia with a low parathyroid hormone; OR
 - C. Acquired and/or inherited disorders in the metabolism of 25(OH)D and phosphate; OR
 - D. Tumor induced osteomalacia (oncogenic osteomalacia); OR
 - E. Hereditary phosphate-losing disorders; OR
 - F. Vitamin D-dependent rickets type 1 (also known as pseudo-vitamin d deficient rickets); OR
 - G. Vitamin D-resistant rickets; OR
 - H. Chronic granuloma-forming disorders; OR
 - I. Lymphomas.

Note: Vitamin D, 1, 25-dihydroxy (CPT code 82652) is primarily indicated during patient evaluations for hypercalcemia and renal failure. It should not be ordered in addition to Vitamin D, 25-hydroxy.

3. Vitamin D deficiency testing services are considered not medically necessary for any conditions other than those listed above. The scientific evidence has not been established for other services, including but not limited to:
 - Routine general population screening and testing for individuals 18 to 65 years of age
 - Individuals with no known signs or symptoms of vitamin D deficiency
 - Individuals with non-skeletal diseases (e.g., cardiovascular disease, cancer, and autoimmune disease)
4. Frequency of Testing
 - Once shown to be vitamin deficient, a patient can be tested up to three (3) times per year for Vitamin D 25-hydroxy (CPT code 82306) only to ensure adequate replacement has been accomplished. Thereafter, annual testing may be appropriate depending upon the indication and other mitigating factors.
 - Vitamin D 1, 25-dihydroxy (CPT code 82652) can be tested up to two (2) times per year.
5. Post-payment Audit Statement

The medical record must include documentation that reflects the medical necessity criteria and is subject to audit by Highmark WholecareSM at any time pursuant to the terms of your provider agreement.
6. Place of Service

The proper place of service for Vitamin D Deficiency screening is on an outpatient basis.

Coverage Determination

The Centers for Medicare and Medicaid Services (CMS) has issued the following guidance:

- Local Coverage Determination (LCD) for Assays for Vitamins and Metabolic Function (L34914)
- Local Coverage Article (LCA) for the Vitamin and Metabolic Assay billing and coding (A56416)

Summary of Literature

Vitamin D (also referred to as “calciferol”) is a fat-soluble vitamin that is naturally present in a few foods, added to others, and available as a dietary supplement. It is also produced endogenously when ultraviolet (UV) rays from sunlight strike the skin and trigger vitamin D synthesis (NIH, 2022).

Vitamin D promotes calcium absorption in the gut and maintains adequate serum calcium and phosphate concentrations to enable normal bone mineralization and to prevent hypocalcemic tetany (involuntary contraction of muscles, leading to cramps and spasms). It is also needed for bone growth and bone remodeling by osteoblasts and osteoclasts. Without sufficient vitamin D, bones can become thin, brittle, or misshapen. Vitamin D sufficiency prevents rickets in children and osteomalacia in adults. Together with calcium, vitamin D also helps protect older adults from osteoporosis (NIH, 2022).

Osteoporosis is a skeletal disease of bone thinning and compromised bone strength and continues to be a major public health issue as the population ages. This disease is characterized by bone fragility and an increased susceptibility to fractures, especially of the spine and hip, although any bone can be affected. It is estimated that over 10 million Americans over the age of 50 have osteoporosis. Risk for osteoporosis has been reported in people of all ethnic backgrounds. Vitamin D has long been recognized as an important and required nutrient for bone health and maintenance. The continuation of vitamin D in a patient with bone loss is critical for optimal care (Sunyecz. 2008).

Per the Endocrine Society, Vitamin D deficiency is defined as a 25(OH)D below 20 ng/ml (50 nmol/liter) and Vitamin D insufficiency as a 25(OH) D of 21–29 ng/ml (52.5– 72.5) nmol/liter. The Institute of Medicine (IOM), officially sets dietary reference intakes based on a thorough review of all available evidence, concluded that a Vitamin D blood level of 20 ng/mL provides enough Vitamin D for keeping bones healthy. Some experts define Vitamin D deficiency as below 20 nanograms per milliliter (ng/mL), others set it below 50 ng/mL (Corliss, 2014).

According to the U.S. Preventative Task Force (USPSTF), there little evidence to support Vitamin D testing for the screening purposes in community-dwelling, nonpregnant, asymptomatic adults age 18 years and older. In the 2015 recommendation update regarding screening for Vitamin D deficiency in adults, the USPSTF concluded, that the current evidence is insufficient to assess the balance of benefits and harms of screening for vitamin D deficiency in asymptomatic adults.” The USPSTF concluded that there is insufficient current evidence to assess the balance of benefits and harms of Vitamin D supplementation, for the primary prevention of fractures in men and premenopausal/postmenopausal women. These recommendations do not apply to individuals with a history of osteoporotic fractures, increased risk of falls, or a diagnosis of osteoporosis or Vitamin D deficiency. The USPSTF also concludes that the current evidence is insufficient to assess the balance of the benefits and harms of daily supplementation with doses greater than 400 IU of vitamin D and greater than 1000 mg of calcium for the primary prevention of fractures in community-dwelling, postmenopausal women. (USPTF, 2021).

A Choosing Wisely initiative was completed by reputable clinicians within the American Board of Internal Medicine (ABIM); to generate recommendations on the appropriate use of Vitamin D deficiency testing. The recommendations state several clinical determinants that use Vitamin D deficiency testing in excess and advises simple changes to supplement Vitamin D, such as more sun, smoking cessation, weight loss, and physical activity. Vitamin D testing will likely be unhelpful and are unlikely to change advice from a physician for high-risk diseases, like Type 2 diabetes and heart disease. Clinicians do think Vitamin D testing is warranted for conditions, such as osteoporosis, celiac disease, kidney disease, liver disease,

pancreatitis, etc. Unnecessary use of Vitamin D deficiency testing leads to treatments that can damage your kidneys and other organs or treatments that are not needed (ABIM, 2014).

The American Academy of Pediatrics (AAP) Committee on Nutrition determined there was insufficient evidence to recommend universal screening of Vitamin D deficiency. The AAP report advises screening for Vitamin D deficiency “only in children and adolescents with conditions associated with reduced bone mass and/or recurrent low-impact fractures. More evidence is needed before recommendations can be made regarding the screening of healthy black and Hispanic children or children with obesity (AAP, 2014).

American Society for Clinical Pathology and Choosing Wisely recommends not performing population-based screening for 25-OH-Vitamin D deficiency. Vitamin D deficiency is common in many populations, particularly in patients at higher latitudes, during winter months and in those with limited sun exposure. Over the counter Vitamin D supplements and increased summer sun exposure are sufficient for most otherwise healthy patients. The Institute of Medicine, which officially sets dietary reference intakes based on a thorough review of all available evidence has concluded that a Vitamin D blood level of 20 ng/mL provides enough Vitamin D for keeping bones healthy. There is little data that shows any benefit in individuals increasing the supplementation of Vitamin D above 30 ng/mL, but some laboratories are recommending potentially dangerous ranges above 50 ng/mL (Corliss, 2014).

Assessing vitamin D status by measuring serum 25(OH)D concentrations is complicated by the considerable variability of the available assays (the two most common ones involve antibodies or chromatography) used by laboratories that conduct the analyses. As a result, a finding can be falsely low or falsely high, depending on the assay used and the laboratory. The international Vitamin D Standardization Program has developed procedures for standardizing the laboratory measurement of 25(OH)D to improve clinical and public health practice. Screening for vitamin D status is becoming a more common part of the routine laboratory bloodwork ordered by primary-care physicians, irrespective of any indications for this practice. No published studies have examined whether such screening for vitamin D deficiency results in improved health outcomes (NIH, 2022).

Specific types of cancer are considered for Vitamin D deficiency testing, such as breast cancer, prostate cancer, and specific types of lymphomas. Low Vitamin D deficiency levels may exacerbate malignancies and high Vitamin D levels may correct certain adverse effects of cancer treatment. Chemotherapy is another factor that may significantly reduce Vitamin D levels. Patients on chemotherapy drug regimens were 400 percent more likely to show severely depressed levels of the vitamin compared to patients not on chemotherapy drug regimens (Evers, 2012). A Cochrane systematic review was concluded and assessed the benefits and harms of Vitamin D supplementation on the prevention of cancer in adults (Bjelakovic, et al, 2014). The review did not show any evidence of effect of Vitamin D levels less than 20 ng/mL or greater at enrollment. The Institute of Clinical Systems Improvement (ICSI) Healthcare Guidelines: Preventative Services recommends that adults get an adequate intake of Vitamin D and calcium in order to prevent either cancer or bone fractures.

Confusion, apathy, recurrent vomiting, abdominal pain, polyuria, polydipsia, and dehydration are the most often noted clinical symptoms of vitamin D toxicity (VDT; also called vitamin D intoxication or hypervitaminosis D). VDT and its clinical manifestation, severe hypercalcemia, are related to excessive long-term intake of vitamin D, malfunctions of the vitamin D metabolic pathway, or the existence of coincident disease that produces the active vitamin D metabolite locally. Although VDT is rare, the health effects can be serious if it is not promptly identified. Laboratory testing during routine clinical examinations may reveal asymptomatic hypercalcemia caused by the intake of vitamin D even in doses recommended for the general population and considered safe. The prevalence of VDT is unknown. As a

result of increased intake of vitamin D–containing supplements and the recent information regarding prevalence of the CYP24A1 mutation in the general population (estimated to occur in 1 of 33,000 births), the incidence of VDT may well increase. Caution is advised for people who self-administrate vitamin D at doses higher than recommended for age and body weight (Marcinowska-Suchowierska, Kupisz-Urbańska et al., 2018).

A review of current evidence discussed the use of Vitamin D testing for screening purposes. This paper reported that no study has shown the effectiveness of 25(OH)D screening in certain groups so that any recommendations regarding 25(OH)D testing have a relatively low evidence base and are mostly derived from expert opinions. A high suspicion or diagnosis of rickets or osteomalacia does definitely justify the measurement of serum 25(OH)D concentrations (Pilz, 2019).

The American College of Obstetrics and Gynecology advises that during pregnancy, severe maternal vitamin D deficiency has been associated with biochemical evidence of disordered skeletal homeostasis, congenital rickets, and fractures in the newborn. Currently, there is insufficient evidence to support a recommendation for screening all pregnant women for vitamin D deficiency. For pregnant women thought to be at increased risk of vitamin D deficiency, maternal serum 25-hydroxyvitamin D levels can be considered and should be interpreted in the context of the individual clinical circumstance. When vitamin D deficiency is identified during pregnancy, most experts agree that 1,000–2,000 international units per day of vitamin D is safe. Higher dose regimens used for treatment of vitamin D deficiency have not been studied during pregnancy. Recommendations concerning routine vitamin D supplementation during pregnancy beyond that contained in a prenatal vitamin should await the completion of ongoing randomized clinical trials (ACOG, 2021).
